Additional Notes:

Contaminant Type

Hydrocarbon-based contaminants are chemical substances, primarily composed of hydrogen and carbon atoms, that can pollute the environment, particularly soil and water, when released from industrial processes or accidental spills.

Influent Concentrations & Units

Influent concentration is a measure of the amount of a particular substance present in a fluid entering a system or process, typically expressed in units such as milligrams per liter (mg/L) or parts per million (ppm).

NAPL

Non-Aqueous Phase Liquid (NAPL) is a term used in environmental science to describe certain types of pollutants that are not soluble in water and can exist as a separate liquid phase in the environment.

NEPA NEC Hazardous Location

The National Environmental Policy Act (NEPA) is a key piece of environmental legislation in the United States that requires federal agencies to assess the environmental effects of their proposed actions prior to making decisions. As part of this, the NEC (National Electrical Code) Hazardous Location Class, Division, Group system is used to classify locations with potentially dangerous conditions due to flammable gases or vapors, combustible dusts, or ignitable fibers or flyings. The 'Class' refers to the general nature of hazardous material in the surrounding atmosphere (Class I for flammable gases or vapors, Class II for combustible dust, and Class III for ignitable fibers or flyings). 'Division' indicates the likelihood of hazardous material being present in an ignitable concentration (Division 1 for conditions where hazards are normally present, and Division 2 where hazards are not normally present but may accidentally exist). Finally, 'Group' categorizes the specific type of hazardous material in the location, designated by letters A through G.
